

1 Figure 1 Temporal graphs displaying the frequency of the glycosylation patterns at
2 HA158 and NA88 with respect to the year. All clade 2.3.2.1 sequences were analyzed
3 globally (A) or in Asia, Africa, Europe, and North America (B-E) till 2022.

4
5 Figure 2 Phylogenetic trees of the HA genes of H5N1 AIVs and variation of HA158
6 and NA1-88 glycosylation sites. Phylogenetic trees were generated from the HA
7 sequences of the clade 2.3.2.1 AIVs that were isolated throughout the world (n=2,565)
8 (A), clade2.3.2.1a in Asia (n=720) (B), clade2.3.2.1c in Asia (n=941) (C) via the
9 maximum likelihood (ML) method. The HA trees were constructed according to strains
10 A/turkey/Ontario/84/1983 (A) and A/Goose/Guangdong/1/96 (B-C). Different HA
11 clades were marked in the phylogenetic tree, while the strains with glycosylation at
12 residue HA158/NA88 and viral isolation regions were marked on the right according
13 to different colors. Temporal graphs displaying the frequency of the glycosylation
14 patterns for HA158 and NA88 in China from 2006-2020 (n=291) (D).

15
16 Figure 3 The amino acid molecular polymorphism of HA/NA glycosylations and glycan
17 modeling of HA and NA. Amino acid sequences included HK97, clade 2.3.2.1d YZ,
18 clade 2.3.2.1e DT, clade 2.3.4 SY, A/Hubei/1/2010/clade 2.3.2.1a (old),
19 A/duck/Bangladesh/2020/clade 2.3.2.1a (new), A/barn/swallow/Hong
20 Kong/1161/2010/clade 2.3.2.1b, A/duck/Vietnam/NCVD/0004/2013/clade 2.3.2.1c,
21 and A/bobcat/Wisconsin/2022/clade 2.3.4.4b. The HA number refers to the H5 number
22 (The H5-158/H3 number here is H5-170) (A). NA88 amino acid patterns (NA88

23 contains NA truncation) (B). The glycan complex was added at the glycosylation sites
24 with a black module (A-B). *In silico* model of N-linked glycan structures mapped onto
25 the HA (HA PDB:6pcx) (C) and NA (NA PDB:3cl2) (D) structures. HA158 is indicated
26 in by dark blue, and NA88 is indicated by purple.

27

28 Figure 4 The HI (A-C) and NT (D-F) titers against Re-6, Re-10, and Re-12 antisera for
29 the HA/NA glycosylation H5N1 variants. $**P < 0.01$.

30

31 Figure 5 Receptor binding specificity of HA/NA glycosylation H5N1 variants. The
32 direct binding affinity of viruses to sialylglycopolymers containing either 3'SLN-PAA
33 or 6'SLN-PAA was measured. SY(A) and CA09(B) were used as controls. The α -2,3(C)
34 and α -2,6(D) binding affinities of YZ and the variants were determined accordingly.

35

36 Figure 6 NA activities of mutant NA proteins and recombinant viruses. Cell lysates
37 were prepared after transfection of pHW-NA plasmid into 293T cells. The sialidase
38 activity of each NA mutant was measured using the soluble NA-XTD substrate (A).
39 Virus samples were standardized to equivalent HA titers. NA activities were compared
40 to those of wild type NA protein or virus samples (B). Two-fold dilutions of each NA
41 mutant were incubated at 37 °C with an equal volume of chicken erythrocytes. The
42 samples were then transferred to 37 °C, and their HA titers were recorded every 2 h to
43 evaluate viral elution speed (C). All data were compared to the value of the YZ-HA158-
44 NA88+, $**P < 0.01$ and $^{ns}P > 0.05$.

45

46 Figure 7 Thermal stability of the recombinant viruses at 37 °C (A), 42 °C (B), and 56 °C
47 (C) and low-pH stability from pH 4.0-7.0 (D). All data were compared to the value of
48 the YZ-HA158-NA88+, * $P < 0.05$, ** $P < 0.01$.

49

50 Figure 8 Growth characterization of the recombinant viruses. Plaque morphologies of
51 the recombinant viruses were determined in MDCK cells (A). Growth kinetics of the
52 recombinant viruses were determined in CEF, MDCK, and A549 cells at a MOI of 0.001
53 (B). Data are presented as the average of virus titrations conducted in triplicates for
54 every 12 h as indicated by TCID₅₀ in CEF cells. All data were compared to the value of
55 the YZ-HA158-NA88+, * $P < 0.05$, ** $P < 0.01$.

56

57 Figure 9 Pathogenicity of the HA/NA glycosylation variants in chickens. Eight five-
58 week-old SPF chickens in each group were inoculated with 200 μL of 10^{4.0} EID₅₀
59 mutant virus, and the mortality rates were observed and recorded until 14 days post-
60 infection (A). The heart, liver, spleen, lung, and kidney of three infected chickens were
61 collected at 36 hours post-infection in PBS containing antibiotics. The viral titers of
62 tissue with same weight were determined in CEF cells (B).

63

64 Figure 10 Pathogenicity of the HA/NA glycosylation variants in mice. BALB/c mice
65 (n=5) were inoculated intranasally with 10¹ to 10⁴ EID₅₀ of virus. Body weight changes
66 (A-D) and mortality (E-H) of the mice were observed continuously for 14 days.
